Academic Year 2014 - 15

"Renewable Energy Systems: Design,  
Development and Optimization"

Kapagiannidis Anastasios

Subject:

Anaerobic digestion of sewage sludge for biogas production

Introduction & Motivation:

Anaerobic Digestion (AD) is a biochemical process during which complex organic matter is decomposed in the absence of oxygen, by various types of anaerobic microorganisms. On the other hand, sewage sludge is the main by-product generated in any wastewater treatment plant (WWTP) for municipal or industrial wastewater. The generated volume of the sludge is predicted to increase continuously in the next decade because more WWTPs will be put into operation with upgraded effluent quality requirements. AD has been widely used as a main process for the treatment of biosolids, for its ability to reduce the amount of sludge solids, further transform organic matter into biogas and limit possible odour problem associated with residual putrescible matter. The capability to recover energy from waste biomass provides AD a more promising prospective.

## **Implementation & Means:**

- Fundamentals and applications of anaerobic digestion for treatment of biosolids
- Sewage sludge types, production volume, composition, treatment, disposal and exploitation possibilities
- Review of AD implementations for sewage sludge treatment
- Basic AD reactor features and operational aspects
- Co-operation with a local municipal wastewater treatment plant for the conceptual design of a AD reactor treating the excess sludge stream with a view to energy production via biogas recovery
- Basic design an operational analysis of the proposed scheme
- Cost analysis and sustainability of the AD reactor implementation
